BANANA PROTEINS, DNA, AND DNA REGULATORY ELEMENTS ASSOCIATED WITH FRUIT DEVELOPMENT

BACKGROUND OF THE INVENTION

5

Field of the Invention

The present invention relates to genes which are differentially expressed during banana fruit development, the protein products of these genes, and DNA regulatory elements which are differentially expressed during banana fruit 10 development.

Description of the Related Art

Bananas represent a crop of great importance to both the world economy and as a means of supplying subsistence to a large portion of the world's 15 population. The global banana export market is about 10% of the world's production with a \$4 billion dollar value. Banana fruit are the fourth most important food in the developing world (May, GD et al. (1995) *Biotechnology* 13:486-492) with approximately 100 million people acquiring their main energy source from bananas. Bananas, like kiwifruit, papayas, and apples, are 20 climacteric fruit, meaning they ripen in association with an ethylene signal. In the ripening process, starch degradation is associated with a respiratory climacteric in the fruit. Banana fruit ripening is characterized by a number of biochemical and physiological changes including fruit softening, changes in peel color and an increase in respiratory activity (Seymour, GB (1993) *in:* Seymour 25 GB, et al. (eds) *Biochemistry of Fruit Ripening*, pp 83-106. Chapman & Hall, London). Although ethylene is produced by the fruit, ripening can also be stimulated by the application of exogenous ethylene. Alternatively, endogenous ethylene production may be stimulated, e.g., by exposing fruit to acetylene.

More specifically, the post-harvest physiology of the banana (*Musa acuminata* cv. Grand Nain) is characterized by initial harvest, a green storage 30 phase, followed by a burst in ethylene production that signals the beginning of the climacteric period. Associated with this respiratory climacteric is a massive conversion of starch to sugars in the pulp, during which the activities of enzymes

SUBSTITUTE SHEET (RULE 26)

-2-

involved in starch biosynthesis decrease while those involved in starch breakdown and mobilization increase rapidly (Wu et al. (1989) *Acta Phytophysiol. Sin.* 15:145-152; Agravante et al. (1990) *J. Jpn. Soc. Food Sci. Technol.* 37:911-915; Iyare et al. (1992) *J. Sci. Food Agric.* 58: 173-176; Cordenunsi et al. (1995), *J. Agric. Food Chem.* 43:347-351; Hill et al. (1995) *Planta* 196:335-343 and 197:313-323). In addition, the rate of respiration rises sharply (Beaudry et al. (1987) *Plant Physiol.* 8:277-282; Beaudry et al. (1989) *Plant Physiol.* 91:1436-1444).

Other changes that occur during ripening include: fruit softening as a result of enzymatic degradation of structural carbohydrates (Agravante et al. (1991) *J. Jpn. Soc. Food Sci. Technol.* 38:527-532; Kojima et al. (1994) *Physiol. Plant.* 90:772-778); a decline in those polyphenol compounds responsible for the astringency of the green unripe fruit which are catalyzed by polyphenol oxidase and peroxidases (Mendoza et al. (1994) in I Uritani et al., eds., *Postharvest Biochemistry of Plant Food-Materials in the Tropics*. Japan Scientific Societies Press, Tokyo, pp 177-191); an increase in the activity of alcohol acetyltransferase, the enzyme that catalyzes the synthesis of isoamyl acetate - the major aroma compound of banana fruit (Harada et al. (1985) *Plant Cell Physiol.* 26:1067-1074); and a de-greening of the peel as a result of chlorophyll breakdown by chlorophyllase (Thomas et al. (1992) *Int. J. Food Sci. Technol.* 27:57-63). Stages of banana fruit ripening are scored by peel color index (PCI) numbers, on a scale from 1 - very green, to 7 - yellow-flecked with brown flecks (Color Preferences Chart, Customer Services Department, Chiquita Brands, Inc.,). PCI can be correlated with other biochemical and physiological parameters associated with fruit development and ripening such as ethylene biosynthesis and respiratory rate. The respiratory rate usually peaks at PCI 2 and PCI 4, respectively, in ethylene-treated bananas (Agravante et al. (1991) *supra*).

Associated with the respiratory climacteric is a large increase in the rate of protein synthesis (Mugugaiyan (1993) *Geobios*, 20:18-21), as well as differential

-3-

protein accumulation (Dominguez-Puigjaner et al. (1992) *Plant Physiol.* 98:157-162). Poly-galacturonase (PG) has been identified as a protein that increases in banana pulp during ripening, as determined by 2-D gel electrophoresis and immuno-hybridization (*id.*). Many of the changes that occur during ripening require de novo protein synthesis (Areas et al. (1988) *J. Food Biochem.* 12:51-60); therefore, a secondary approach to investigate changes that occur during ripening is to isolate transcripts encoding proteins associated with the ripening process. Analogous studies of differential gene expression have been successfully employed in other plant species.

Other enzymes associated with developing and ripening of fruit include proteinase inhibitors and chitinases (Dopico et al. (1993) *Plant Molec. Bio.* 21:437), stress-related enzymes (Ledger et al. (1994) *Plant Molec. Biol.* 25:877), β -oxidation pathway enzymes (Bojorquez et al. (1995), *Plant Molec. Biol.* 28:811), and metabolite-detoxifying enzymes (Picton et al. (1993) *Plant Molec. Biol.* 23:193). Chitinases are abundant proteins found in a wide variety of plants. Although chitinases are produced by a diversity of plant species, the presence of chitin has not been reported in higher plants. Since chitin is the major structural component of fungal cell walls, it has been proposed that chitinases serve as defense proteins with antifungal activity. Chitinases are reported to be induced in higher plants by a number of different types of stress (Linthorst (1991) *Crit. Rev. Plant Sci.* 10:123; Punja et al. (1993) *J. Nematol.* 25:526; Collinge et al. (1993) *Plant J.* 3:31). Many plant chitinases are expressed constitutively, although at a low level.

As noted above, in ripening climacteric fruit, starch degradation is associated with a respiratory climacteric in the fruit. Reactive oxygen species (ROS) are byproducts of cellular respiration, especially under conditions which result in high levels of NADH. ROS generation during respiration may be at the site of ubiquinones in the electron transport chain. Both yeast and mammalian metallothioneins may play a direct role in the cellular defense against oxidative

-4-

stress by functioning as antioxidants (Dalton et al. (1994) *Nucl. Acids Res.* 22:5016-5203; Tamai et al. (1993) *Proc Nat Acad Sci (USA)* 90:8013-8017; Bauman et al. (1991) *Toxicol. Appl. Pharmacol.* 110:347-354). MT may play an additional role in supplying metal ions to Cu- and Zn-superoxide dismutase 5 (SOD), an enzyme that catalyzes the disproportionation of superoxide anion to hydrogen peroxide and dioxygen and is thought to play an important role in protecting cells from oxygen toxicity.

Transcripts encoding MT or MT-like proteins have been isolated from many different plants (recently reviewed in Robinson et al. (1993) *Biochem J.* 10 295:1-10). There is accumulating evidence that the plant MT mRNAs are translated, and the protein may have a function in the plant tissues from which transcripts have been isolated. A seed-associated polypeptide (E_c protein) has been purified from wheat and sequenced (Kawashima et al. 1992), and more recently, MT was reported to have been isolated from *Arabidopsis* (meeting abstract). Based on deduced amino acid sequences, plant MT proteins are approximately 70 aa and have characteristic cysteine-rich regions at the N and C termini, separated by a variable spacer region. Based on the number and distribution of the cysteine residues, plant MTs have been classified into two distinct types (Robinson et al. (1993), *supra*). Type 1 MTs have 6 N-terminal and 15 6 C-terminal cysteine residues, whereas type 2 have 8 cysteine residues in the N-terminal domain and 6 at the C-terminus. Although there are no strict patterns of MT expression, in general type 1 transcript abundance is high in roots, and is often metal-inducible, whereas type 2 is expressed primarily in leaves. Other transcripts have been isolated that encode proteins with homology to plant MTs 20 but cannot be classified as either type 1 or type 2, and these include seed-specific proteins or transcripts from barley and wheat (see, Robinson et al. (1993), *supra*). In *Arabidopsis thaliana*, MT proteins are encoded by a gene family containing 25 five members, two copies encoding a type 2 MT and 3 encoding a MT with homology to type 1 (Zhou et al. (1995) *Mol. Gen. Genet.* 248:318-328).

-5-

In plants transcripts encoding metallothionein-like proteins have often been isolated by differential screening. Type 2 MT have recently been isolated from plants expressed in association with senescence, leaf abscission (Coupe et al.

(1995) *Planta* 197:442-447), and fruit ripening (Ledger et al. (1994) *Plant Molec.*

- 5 *Biol.* 25:877-886). Using differential screening, Ledger and Gardner (*id.*) found transcripts encoding MT-like proteins in developing kiwifruit. One, pKIWI503, was specifically upregulated late in fruit development, during ripening of the mature fruit.

A major component of the export market is the level of ripening control
10 which is exerted by modern banana shipping systems. Bananas for export must be shipped under refrigeration at 12-14°C, often under controlled atmosphere (CA) conditions (*i.e.*, low oxygen combined with CO₂), which reduces the effects of ethylene produced by the fruit. Exposure to ethylene for 24 hours at concentrations of 100-1000 µl per liter is used to trigger the ripening climacteric.

15 This "gassing" step is typically done near the final point in the distribution system. Although this system is entirely functional, resulting in marketability of high quality fruit with minimal losses, there remains a role for engineered ethylene control in the banana export market. Bananas for export are harvested green at approximately 75% of full size. This is done to ensure, even with the use of low temperature and CA, that few if any of the bananas start ripening during shipment.
20 Allowing the bananas to remain on the plant longer would result in more carbohydrate accumulation to the fruit and a direct, zero cost increase in yield. If engineered ethylene control were implemented in banana, this increased yield would come at no increased risk of premature ripening during shipment.

25 Moreover, linking exogenous genes to isolated gene promoters that are differentially expressed during banana ripening, and in response to ethylene, would allow for the production of exogenous protein in banana tied to the ripening process, and in other plants, controlled by ripening or exposure to ethylene.

-6-

SUMMARY OF THE INVENTION

Accordingly, a major object of the present invention is to provide isolated and purified genes which are differentially expressed during banana fruit development, and to provide the protein products of these genes.

5 A further object of the present invention is to provide DNA regulatory elements which are differentially expressed during banana fruit development, and chimeric genes comprising these DNA regulatory elements operably linked to heterologous DNA molecules, and plants transformed with said chimeric genes, providing for controlled expression of said heterologous DNA molecules during
10 the development of the fruit of said plants, or in response to exogenous development signals, such as ethylene signals in said plants.

A still further object of the present invention is to provide a method for expression of a heterologous protein in fruit comprising transforming fruiting plants with one or more chimeric genes according to the present invention,
15 exposing said fruit to the appropriate natural or exogenous development signal, such as an ethylene signal, and harvesting fruit containing said heterologous protein. The method of the present invention may further comprise isolating the proteins produced by said method from the harvested fruit. In a particularly preferred embodiment, the heterologous protein is a therapeutic protein, which
20 may be isolated from the harvested fruit, or consumed directly in the transformed fruit by a patient in need of said therapeutic protein.

With the foregoing and other objects, advantages and features of the invention that will become hereinafter apparent, the nature of the invention may be more clearly understood by reference to the following detailed description of the
25 preferred embodiments of the invention and to the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1. Relative abundance of ripening-associated transcripts in banana pulp at PCI 1, 3 and 5. Plasmids containing the indicated cDNA were affixed to

-7-

nylon membrane and hybridized with pulp radio-labeled first-strand cDNAs. Relative transcript abundance is expressed in arbitrary units (AU).

Figure 2. Northern analyses of total RNA from pulp and peel (at PCI 3), root,
5 corm, and leaf tissues hybridized with cDNA probes representing each of
the eleven classes of differentially expressed transcripts. Putative identities
of each transcript are indicated to the left of the panel.

Figure 3. Total banana pulp protein extract at different stages of ripening,
10 separated by SDS-PAGE and stained with Coomassie blue. Protein
profiles during ripening show the presence of an abundant protein of 31
kDa that decreases in relative abundance during ripening.

Figure 4. Western blot analysis of total soluble protein extracted from different
banana tissues and hybridized with polyclonal antiserum against purified
15 P31. The antiserum detects a 31 kDa protein in pulp which is not present
in peel, meristem, leaf, corm, or root tissue.

Figure 5. Expression of P31 (top panel) and pBAN3-30 (bottom panel) in banana
pulp during ripening. Total protein and RNA were isolated from banana
pulp at each of seven stages of banana fruit ripening (PCI 1 through 7,
numbered at top of figure). Pulp proteins were separated by SDS-PAGE
20 and hybridized with the P31 antiserum. Total RNA (10 µg per lane) was
separated by agarose gel electrophoresis and transferred to nylon
membrane, and hybridized with a ³²P-labeled banana chitinase cDNA probe
(pBAN3-30). Both the P31 protein and the corresponding chitinase
transcript at 1.2 kilobases are abundant in pulp during the early stages of
25 ripening by decrease as ripening progresses.

Figure 6. Western blot analysis of the translation products of four banana chitinase
cDNA clones homologous to pBAN3-30 expressed as fusion proteins with
 β -galactosidase in pBluescript and hybridized with P31 antiserum. The
polyclonal antiserum recognizes a 35 kDa polypeptide in bacterial cultures

-8-

containing in-frame cDNA inserts (pBAN3-36 and pBAN3-45) that is not present in bacterial cells containing either the pBluescript cloning vector without an insert (no insert) or chitinase cDNA inserts that are not in-frame with the β -galactosidase gene (pBAN3-30 and pBAN3-31).

5 Figure 7. Complete nucleotide sequence of the cDNA clone pBAN3-30 and deduced amino acid sequence of the pBAN3-30 translation product. The N-terminal amino acid sequence obtained from purified P31 is aligned with the translation product and underlined, and is identical to the deduced amino acid sequence of pBAN3-30 at 17 of 20 residues. The translation initiation codon ATG starting at position 55 of pBAN3-30 is underlined as well as the in-frame stop codon at position 1024. Other features of the cDNA sequence include several putative polyadenylation signals between positions 1136 and 1148 (underlined).

10

15 Figure 8. Amino acid alignments of A) amino- and B)-carboxy-terminal regions of banana P31 with class III acidic chitinase sequences from chickpea (*Cicer arietinum*, 16), grape (*Vitis vinifera*, Busam et al. unpublished), *Arabidopsis thaliana* (17), tobacco (*Nicotiana tabacum*, 18), sugar beet (*Beta vulgaris*, 19). Dots indicate the amino acid residues identical to the banana P31 amino acid sequence on the top line. Dashes indicate gaps introduced to aid the alignment. A) Amino-terminal alignment illustrates the lack of sequence homology of the signal-peptide sequence of plant chitinases. B) The carboxy-terminal region indicates the 18 residue C-terminal extension unique to the banana P31 sequence.

20

Figure 9. cDNA sequences of MT F-1 and F-3.

25 Figure 10. A) Alignment of deduced amino acid sequences of banana and kiwifruit, apple and papaya fruit-associated metallothionein-like proteins. Alignment was performed using Clustal (default settings). Amino acid alignment of fruit-associated MTs. Asterisks above the sequence indicate the pattern of conserved cysteine residues. A dash denotes a gap inserted

-9-

in the sequence to aid in alignment. A dot indicates that the amino acid in
that position is identical to the banana F1 sequence on the top line. (The
total number of amino acids is indicated in parentheses at the end of the
sequence.) B) Phylogenetic tree of plant MT sequences indicating that the
5 fruit-associated MT are distinct from MT1 and MT2. GenBank Accession

Figure 11. Northern blot analysis of MT transcript distribution in banana. Total
RNA (5 µg/lane) from different banana tissues was separated in a
15 formaldehyde-containing 2% agarose gel, transferred to nylon membrane,
and hybridized with an F1 or F3 cDNA probe. The large transcript
hybridizes more strongly to the F1 probe, and is approximately 540 bases.
The smaller transcript hybridizes more strongly to the F3 cDNA probe,
and is approximately 370 bases. Lane labels: Pu = pulp; Pe = perl; R =
20 root; C = corm; L = leaf.

Figure 12. Restriction maps of MT genomic clones. The maps represent the
coding region and at least 1kb of flanking DNA. The approximate scale is
indicated by a dark bar.

Figure 13. Nucleotide sequence of MT F3 genomic clone, from the 5' HindII site
25 to the 3' Sall site. A 10-base 5' sequence motif beginning at -313 from the
translation start site (in capital letters) shares homology with an antioxidant
response element. The putative TATA box (starting at position -96 from
the translation start site) is underlined, and the three exons (beginning from
the translation start site) are depicted in capital letters. At the 3' end of the

-10-

sequence, the stop codon is underlined, as well as a potential polyadenylation signal (TAAATAAA).

Figure 14. Relative MT transcript abundance in banana pulp-derived protoplasts increases in the presence of hydrogen peroxide but not metal ions, as compared to the untreated control. RNA dot-blots were hybridized to the F3 cDNA probe and hybridization signal intensity, expressed in arbitrary units (AU), was normalized to 18S rRNA as a measure of total RNA loaded.

15

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS OF THE INVENTION

The present invention provides isolated and purified banana proteins which are differentially produced in banana fruit during ripening. In a preferred 20 embodiment, said proteins are selected from the group consisting of starch synthases, granule-bound starch synthases, chitinases, endochitinases, β -1,3 glucanases, thaumatin-like proteins, ascorbate peroxidases, metallothioneins, lectins, and other senescence-related genes.

The proteins of the present invention may be isolated from ripening fruit 25 using protein purification methods well known in the art. In particular, fruit containing the protein of the present invention may be subjected to chromatographic techniques which separate proteins present in the extract according to size, affinity and charge. Fractions obtained from each chromatographic step are analyzed for the desired enzymatic activity and subjected

-11-

to further purification steps. A particularly preferable method for obtaining purified proteins according to the present invention is high performance liquid chromatography (HPLC).

After a protein according to the present invention has been purified, its
5 amino acid sequence can be determined using amino acid sequencing methods well known in the art. A particularly preferable method is Edman degradation. Having obtained sequence information on the protein of the present invention, one can design oligonucleotide probes for isolating the DNA encoding the protein of the present invention, using conventional screening methods, or amplification
10 methods such as polymerase chain reaction (PCR). It is particularly preferable to design such oligonucleotides in a completely degenerate manner, such that oligonucleotides containing each codon encoding a particular amino acid are present in the oligonucleotide mix. Alternatively, inosine can be used at positions in the codon where degeneracies are known to be present. In a particularly
15 preferred embodiment, the proteins of the present invention are encoded by a DNA molecule selected from the group consisting of clones pBAN 3-33, pBAN 3-18, pBAN 3-30, pBAN 3-24, pBAN 1-3, pBAN 3-28, pBAN 3-25, pBAN 3-6, pBAN 3-23, pBAN 3-32, and pBAN 3-46.

The present invention thus further provides an isolated and purified banana
20 DNA molecule which is differentially expressed in banana fruit during ripening. More specifically, the present invention provides a DNA molecule which is differentially expressed in banana fruit during ripening, wherein said DNA molecule encodes a protein selected from the group consisting of a starch synthase, a granule-bound starch synthase, a chitinase, an endochitinase, a β -1,3
25 glucanase, a thaumatin-like protein, an ascorbate peroxidase, a metallothionein, a lectin, or another senescence-related gene. In a particularly preferred embodiment, these DNA molecules are the clones pBAN 3-33, pBAN 3-18, pBAN 3-30, pBAN 3-24, pBAN 1-3, pBAN 3-28, pBAN 3-25, pBAN 3-6, pBAN 3-23, pBAN 3-32, and pBAN 3-46. In another preferred embodiment, the DNA

-12-

molecule of the present invention has a nucleotide sequence selected from the group consisting of SEQ ID NO: 1; SEQ ID NO: 2; and SEQ ID NO: 3.

In general, the procedures for isolating the DNA encoding a protein according to the present invention, subjecting it to partial digestion, isolating
5 DNA fragments, ligating the fragments into a cloning vector, and transforming a host are well known in recombinant DNA technology. Accordingly, one of ordinary skill in the art can use or adapt the detailed protocols for such procedures as found in Sambrook et al. (1989), *Molecular Cloning: A Laboratory Manual*, 2nd. Ed., Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, 3 volumes,
10 or in any other manual on recombinant DNA technology.

Once the gene encoding a protein of the present invention has been obtained from one species, it can serve as a hybridization probe to isolate corresponding genes from the other species by cross-hybridization under low to moderate stringency conditions. Such conditions are usually found empirically by
15 determining the conditions wherein the probe specifically cross-hybridizes to its counterpart gene with a minimum of background hybridization. Nucleic acid hybridization is a well known technique and thoroughly detailed in Sambrook et al.

As noted above, the DNA encoding the proteins of the present invention
20 can be originally isolated using PCR. Corresponding DNAs from other species can also be isolated using PCR, and oligonucleotides for performing these subsequent PCR reactions can be optimized using the sequence information obtained from DNA cloned from the first species.

Moreover, peptides and fragments as well as chemically modified
25 derivatives of the proteins of the present invention are also contemplated by the present invention. Briefly, any peptide fragment, derivative or analog which retains substantially the same biological activity of the protein of the present invention, and is differentially produced during fruit ripening, is contemplated. An analog may be defined herein as a peptide or fragment which exhibits the

-13-

biological activity of the protein of the present invention, and which is differentially expressed during fruit ripening, but which has an amino acid substitution, insertion or deletion in comparison to the wild-type protein. Such an analog can be prepared by the "conservative" substitution of an amino acid having 5 similar chemical properties. One of ordinary skill in the art can readily identify suitable substitutions.

Thus, it should also be appreciated that also within the scope of the present invention are DNA sequences encoding a protein according to the present invention having the same amino acid sequence as the wild-type protein, but also 10 those DNA sequences which are degenerate to the wild-type sequence. By "degenerate to" is meant that a different three-letter codon is used to specify a particular amino acid. It is well known in the art that the following codons can be used interchangeably to code for each specific amino acid:

	<u>Amino Acid</u>	<u>Abbrev.</u>	<u>Codons</u>
15	Phenylalanine	(Phe or F)	UUU, UUC
	Leucine	(Leu or L)	UUA, UUG, CUU, CUC, CUA, CUG
	Isoleucine	(Ile or I)	AUU, AUC, AUA
	Methionine	(Met or M)	AUG
	Valine	(Val or V)	GUU, GUC, GUA, GUG
20	Serine	(Ser or S)	UCU, UCC, UCA, UCG, AGU, AGC
	Proline	(Pro or P)	CCU, CCC, CCA, CCG
	Threonine	(Thr or T)	ACU, ACC, ACA, ACG
	Alanine	(Ala or A)	GCU, GCG, GCA, GCG
	Tyrosine	(Tyr or Y)	UAU, UAC
25	Histidine	(His or H)	CAU, CAC
	Glutamine	(Gln or Q)	CAA, CAG
	Asparagine	(Asn or N)	AAU, AAC
	Lysine	(Lys or K)	AAA, AAG
	Aspartic Acid	(Asp or D)	GAU or GAC

-14-

<u>Amino Acid</u>	<u>Abbrev.</u>	<u>Codons</u>
Glutamic Acid	(Glu or E)	GAA or GAG
Cysteine	(Cys or C)	UGU or UGC
Arginine	(Arg or R)	CGU, CGC, CGA, CGG, AGA, AGG
Glycine	(Gly or G)	GGU, GGC, GGA, GGG
5 Stop codon		UAA (ochre), UAG (amber), UGA (opal)

It should be understood that the codons specified above are for RNA sequences. The corresponding codons for DNA have T substituted for U.

Mutations can be made in the wild-type sequence such that a particular 10 codon is changed to a codon which codes for a different amino acid. Such a mutation is generally made by making the fewest nucleotide changes possible. A substitution mutation of this sort can be made to change an amino acid in the resulting protein in a non-conservative manner (i.e., by changing the codon from an amino acid belonging to a grouping of amino acids having a particular size or 15 characteristic to an amino acid belonging to another grouping) or in a conservative manner (i.e., by changing the codon from an amino acid belonging to a grouping of amino acids having a particular size or characteristic to an amino acid belonging to the same grouping). Such a conservative change generally leads to less change in the structure and function of the resulting protein. A non- 20 conservative change is more likely to alter the structure, activity or function of the resulting protein. The following is one example of various groupings of amino acids:

Amino acids with nonpolar R groups

	Alanine	Proline
25	Valine	Phenylalanine
	Leucine	Tryptophan
	Isoleucine	Methionine

-15-

Amino acids with uncharged polar R groups

	Glycine	Tyrosine
	Serine	Asparagine
	Threonine	Glutamine
5	Cysteine	

Amino acids with charged polar R groups (negatively charged at pH 6.0)

	Aspartic acid	Glutamic acid
--	---------------	---------------

10 Basic amino acids (positively charged at pH 6.0)

	Lysine	Arginine
--	--------	----------

Histidine (at pH 6.0)

Another grouping may be according to molecular weight (i.e., size of R groups):

	Glycine	75	Aspartic acid	133
15	Alanine	89	Glutamine	146
	Serine	105	Lysine	146
	Proline	115	Glutamic acid	147
	Valine	117	Methionine	149
	Threonine	119	Histidine (at pH 6.0)	155
20	Cysteine	121	Phenylalanine	165
	Leucine	131	Arginine	174
	Isoleucine	131	Tyrosine	181
	Asparagine	132	Tryptophan	204

Another grouping may be those amino acids with phenyl groups:

25	Phenylalanine	Tryptophan
	Tyrosine	

-16-

Particularly preferred substitutions are:

- Lys for Arg and vice versa such that a positive charge may be maintained;
 - Glu for Asp and vice versa such that a negative charge may be maintained;
 - Ser for Thr such that a free -OH can be maintained; and
 - Gln for Asn such that a free NH₂ can be maintained.
- Amino acid substitutions may also be introduced to substitute an amino acid with a particularly preferable property. For example, a Cys may be introduced at a potential site for disulfide bridging with another Cys. A His may be introduced as a particularly "catalytic" site (i.e., His can act as an acid or base and is the most common amino acid in biochemical catalysis). Pro may be introduced because of its particularly planar structure, which induces β-turns in the protein's structure.
- Purification of the proteins of the present invention from natural or recombinant sources can be accomplished by conventional purification means such as ammonium sulfate precipitation, gel filtration chromatography, ion exchange chromatography, adsorption chromatography, affinity chromatography, chromatofocusing, HPLC, FPLC, and the like. Where appropriate, purification steps can be done in batch or in columns.

Peptide fragments of the proteins of the present invention can be prepared by proteolysis or by chemical degradation. Typical proteolytic enzymes are trypsin, chymotrypsin, V8 protease, subtilisin and the like; the enzymes are commercially available, and protocols for performing proteolytic digests are well known. Peptide fragments are purified by conventional means, as described above. Peptide fragments can often be identified by amino acid composition or sequence. Peptide fragments are useful as immunogens to obtain antibodies against the proteins of the present invention .

-17-

In accordance with the present invention, all or a part of a DNA molecule according to the present invention can be stably inserted in a conventional manner into the nuclear genome of a plant cell, and the so-transformed plant cell can be used to produce a transgenic plant showing improved expression of the DNA

5 molecule according to the present invention. In this regard, a disarmed Ti-plasmid, containing a DNA molecule according to the present invention, in *Agrobacterium* (*e.g.*, *A. tumefaciens*) can be used to transform a plant cell using the procedures described, for example, in EP 116.718 and EP 270,822, PCT publication 84.02913, EPA 87400544.0 and Gould et al. ((1991) *Plant Physiol.* 95: 426) which are incorporated herein by reference). Preferred Ti-plasmid vectors contain the foregoing DNA sequence between the border sequence, or at least located to the left of the right border sequence, of the T-DNA of the Ti-plasmid.

10

A DNA molecule according to the present invention may also be operatively linked to a promoter capable of regulating the expression of said DNA molecule, to form a chimeric gene. Said chimeric gene may then be incorporated into a replicable expression vector, as described below, for use in transforming plants. The replicable expression vectors may also be used to obtain the polypeptides of the present invention by well known methods in recombinant DNA technology.

15

20 Replicable expression vectors according to the present invention comprise a nucleic acid encoding the subject gene, i.e., the coding sequence is operably linked in proper reading frame to a nucleotide sequence element which directs expression of a protein of the present invention. In particular, the nucleotide sequence elements may include a promoter, a transcription enhancer element, a termination signal, a translation signal, or a combination of two or more of these elements, generally including at least a promoter element.

25

Replicable expression vectors are generally DNA molecules engineered for controlled expression of a desired gene, especially where it is desirable to produce

-18-

large quantities of a particular gene product, or polypeptide. The vectors comprise one or more nucleotide sequences operably linked to a gene to control expression of that gene, the gene being expressed, and an origin of replication which is operable in the contemplated host. Preferably the vector encodes a
5 selectable marker, for example, antibiotic resistance. Replicable expression vectors can be plasmids, bacteriophages, cosmids and viruses. Any expression vector comprising RNA is also contemplated. The replicable expression vectors of this invention can express the protein of the present invention at high levels.
Many of these vectors are based on pBR322, M13 and lambda and are well known
10 in the art and employ such promoters as *trp*, *lac*, P_L , T7 polymerase and the like. Hence, one skilled in the art has available many choices of replicable expression vectors, compatible hosts, and well-known methods for making and using the vectors.

Other types of vectors can be used to transform plant cells, using
15 procedures such as direct gene transfer (as described, for example, in EP 233,247), pollen mediated transformation (as described, for example, in EP 270,356, PCT publication WO 95/01856, and U.S. Patent No. 4,407,956), liposome-mediated transformation (as described, for example, in U.S. Patent No. 4,5376,475) and other methods such as the methods for transforming monocots
20 described in Fromm et al. ((1990) *Bio/Technology* 8:833) and Gordon-Kamm et al.((1990) *Plant Cell* 2:603).

Preferably, the gene according to the present invention is inserted in a plant genome downstream of, and under the control of, a promoter which can direct the expression of the gene in the plant cells. Preferred promoters include,
25 but are not limited to, the strong constitutive 35S promoter (Odell et al. (1985) *Nature* 313:810) of cauliflower mosaic virus; 35S promoter have been obtained from different isolates (Hull et al. (1987) *Virology* 86:482). Other preferred promoters include the TR1' promoter and the TR2' promoter (Velten et al.(1984) *EMBO J.* 3:2723) Alternatively, a promoter can be utilized which is not

-19-

constitutive but rather is specific for one or more tissues or organs. For example, a gene according to the present invention can be selectively expressed in the green tissues of a plant by placing the gene under control of a light-inducible promoter such as the promoter of the ribulose-1,5-phosphate-carboxylase small subunit gene 5 as described in EPA 8300921.1. Another alternative is to use a promoter whose expression is inducible by temperature or chemical factors.

It is also preferred that a gene according to the present invention be inserted upstream of suitable 3' transcription regulation signals (i.e., transcript 3' end formation and polyadenylation signals) such as the 3' untranslated end of the 10 octopine synthase gene (Gielen et al.(1984) *EMBO J.*, 3:835-845) or T-DNA gene 7 (Velten and Schell (1985) *Nucl. Acids Res.* 13:6981-6998).

The resulting transformed plant of this invention expresses the inserted gene and is characterized by the production of high levels of the gene product. Such a plant can be used in a conventional breeding scheme to produce more 15 transformed plants with the same improved phenotypic characteristics, or to introduce the gene into other varieties of the same or related plant species. Seeds, which are obtained from transformed plants, contain the gene as a stable genomic insert.

The present invention further encompasses compositions comprising one or 20 more proteins according to the present invention, and a carrier therefor.

The present invention also provides isolated and purified banana DNA regulatory elements which are 5' or 3' to a gene which is differentially expressed during banana fruit development. In a preferred embodiment, said DNA regulatory elements are promoters. Said regulatory elements control the 25 expression of genes to which they are operatively linked, and are sensitive to a plant development signal. In a preferred embodiment, the plant development signal is an ethylene signal. The ethylene signal may be ethylene gas released by ripening fruit, either naturally or stimulated artificially; alternatively, the

-20-

ethylene signal is produced by exposure of the plant or fruit to exogenous ethylene gas.

- The DNA regulatory elements of the present invention may be linked to native plant genes via homologous recombination, *e.g.*, via the method of U.S. 5 Patent 5,272,071, the contents of which are incorporated herein by reference. Alternatively, the DNA regulatory elements of the present invention may be operatively linked to a DNA molecule which is desired to be expressed in a plant in response to a development signal, thus forming a chimeric gene. Transformation of plants with such a chimeric gene, as described above, provides 10 for controlled expression in fruit encoded by said DNA molecule. In a particularly preferred embodiment, said DNA molecule encodes a therapeutic protein.

The DNA molecules of the present invention may be used to transform any plant in which expression of the particular protein encoded by said DNA 15 molecules is desired. In addition, the regulatory elements of the present invention may be used to trigger gene expression in any plant in which gene expression is desired. Suitable plants for transformation with the DNA molecules and regulatory elements of the present invention include Banana (*e.g.*, *Musa acuminata*); kiwifruit (*e.g.*, *Actinidia deliciosa*); grape (*e.g.*, *Vitis vinifera*, *V. labrusca*, *V. rotundifolia*); peach, nectarine, plum, apricot, cherry, almond (*e.g.*, *Prunus persica*, *P. domestica*, *P. salicina*, *P. avium*, *P. cerasus*, *P. amygdalus*); pear (*e.g.*, *Pyrus communis*, *P. pyrifolia*); apple (*e.g.*, *Malus x domestica*); eggplant (*e.g.*, *Solanum melongena*); tomato (*e.g.*, *Lycopersicon lycopersicum*, *L. esculentum*); peppers (*e.g.*, *Capciscum sp.*); peas and beans (*e.g.*, *Phaseolus vulgaris*, *P. lunatus*, *P. Limensis*, *Cicer arietimum*, *Vigna angularis*, *Pisum sativum*, *Glycine max*); cucumbers, melons, squash and pumpkins (*e.g.*, *Cucumis melo*, *C. sativus*, *Citrullus lanatus*, *Cucurbita maxima*, *C. pepo*); maize (*e.g.*, *Zea mays*); rice (*e.g.*, *Oryza sativa*); wheat; barley (*e.g.*, *Hordeum vulgare*); tobacco (*e.g.*, *Nicotiana tabacum*); potato (*e.g.*, *Solanum tuberosum*); beet (*e.g.*, *Beta*

-21-

vulgaris); carrot (e.g., *Daucus carota*); parsnip (e.g., *Pastinaca sativa*); turnip, rutabaga (e.g., *Brassica rapa*, *B. napus*); and radish (e.g., *Raphanus sativus*). It will be understood that this is not an exclusive list, but merely suggestive of the wide range of utility of the DNA molecules and regulatory elements of the present invention.

5

The present invention thus also provides a method for expression of heterologous protein in fruit comprising transforming fruiting plants with a chimeric gene, replicable expression vector, or plasmid comprising a ripening-associated promoter, as described above, exposing said fruit to an ethylene signal, 10 and harvesting fruit containing said heterologous protein. The protein may be isolated from the harvested fruit using conventional methods, including those described above. Alternatively, where the protein is a therapeutic protein, in a preferred embodiment the fruit may be directly consumed by a patient in need of the therapeutic protein, thus providing for convenient oral administration of the 15 protein.

10

15

The following examples are presented in order to more fully illustrate the preferred embodiments of the invention. They should in no way be construed, however, as limiting the broad scope of the invention.

20

EXAMPLE 1: Differential Gene Expression in Ripening Banana (*Musa acuminata* cv. Grand Nain) Fruit

The experiments described in this example were designed to isolate those banana genes that are differentially expressed in ripening banana fruit.

25

MATERIALS AND METHODS

Plant Materials

Ethylene treated and untreated banana fruit (*Musa acuminata* cv. Grand Nain) were obtained from the Northside Banana Company (Houston, TX). The pulp and peel of fruit representing each of the seven different stages of ripening

-22-

(PCI 1 through 7) were separated and quick-frozen in liquid nitrogen. Tissues from ten individual fruit were pooled to obtain a uniform representative sample for each ripening stage and ground to a fine powder under liquid nitrogen in a stainless steel Waring blender. Ground samples were stored at -80°C until 5 utilized. Leaf, corm and root tissue were obtained from greenhouse-grown plants (cv Grand Nain), ground in liquid nitrogen using a mortar and pestle, and stored at -80°C.

RNA Isolation

10 Pre-warmed (65°C) RNA extraction buffer (1.4% (w/v) SDS, 2% (w/v) polyvinylpyrrolidone, 0.5 M NaCl, 0.1M sodium acetate, 0.05 M EDTA, pH 8.0, 0.1% (v/v) P-mercaptoproethanol) was added to previously ground samples of pulp from PCI 1 and PCI 3 at a 5:1 tissue to buffer ratio. Samples were homogenized with two or three 30 second pulses of a Polytron tissue homogenizer 15 (Brinkman) and incubated at 65°C for 15 min. Starch and other cell debris were pelleted by centrifugation at 2,400g for 10 min at room temperature and the supernatant transferred to a disposable 50 ml polypropylene screw-cap tube. After the addition of 0.2 vol. of 5 M potassium acetate, pH 4.8, samples were mixed by inversion and incubated on ice for 30 min. The resulting precipitate was pelleted 20 by centrifugation at 20.2k rpm for 10 min at 4°C in a Sorvall SW28 rotor. The supernatant was transferred to a disposable polypropylene centrifuge tube, and the high-molecular weight RNA was precipitated by the addition of lithium chloride to a final concentration of 2.5 M and incubation overnight at 4°C. RNA was isolated from leaf and root tissues using a CTAB isolation buffer modified from 25 Doyle and Doyle (1987). Root and leaf tissues were ground to a powder in liquid nitrogen using a mortar and pestle. Five grams of frozen powder were added to 10 ml of prewarmed (65°C) CTAB RNA extraction buffer (100 mM Tris-Borate, pH 8.2, 1.4 M NaCl, 20 mM EDTA, 2% (w/v) CTAB (hexadecyltrimethyl- ammonium bromide), 0.1% (v/v) β-mercaptoproethanol). Samples were

-23-

homogenized with two or three 30 second pulses of a Polytron tissue homogenizer (Brinkman), and the homogenate was incubated at 65°C for one hour. Samples were cooled to room temperature, extracted twice with an equal volume of chloroform, and the phases were separated by centrifugation. Following 5 centrifugation, lithium chloride was added to a final concentration of 2M, and RNA was allowed to precipitate overnight at 4°C. RNA was pelleted at 4°C for 20 min at 20kg, washed with 70% ethanol and re-suspended in DEPC-treated H₂O. The RNA was phenol:chloroform (1:1) extracted and ethanol precipitated.

10

cDNA Library Construction

Pulp PCI 1 and 3 cDNA libraries were generated using poly(A) + mRNA prepared from total RNA using a magnetic bead separation protocol (Dynal) according to the manufacturer's instructions. Lambda Zap cDNA libraries were 15 generated according to the supplier's protocol (Stratagene).

Differential Screening

Approximately 5 x 10⁴ plaque-forming units (pfu) from each cDNA library were plated onto LB plates using the appropriate *E. coli* host strain. Duplicate 20 plaque-lifts were generated by placing Nytran nylon filters (Schleicher and Schuell) onto plaque-containing plates for one and four minutes for the first and second filters, respectively. Filter-bound DNA was denatured for two min in 1.5 M NaCl, 0.5 M NaOH, and neutralized for four minutes in 1.5 M NaCl, 0.5 M Tris (pH 8.0). Filters were rinsed in 0.5 M Tris (pH 8.0), blotted dry, and UV 25 crosslinked (Stratalinker, Stratagene).

Labeled first-strand cDNA probes used in the differential screening were synthesized from 15 mg total RNA in the presence of 1.5 μm [α -[³²P] dCTP (3000 mCi/mmol) using an oligo(dT)₁₅, primer (Promega) and 15U MMLV reverse transcriptase according to the manufacturer's instructions (Promega). The mRNA

-24-

template was removed by hydrolysis in 100 mm NaOH at 65°C for 30 min. The reaction was neutralized in 100 mm Tris-HCl (pH 8.0), and the labeled first-strand cDNA was ethanol precipitated in the presence of 20 µg of carrier yeast tRNA.

Filters were pre-hybridized for 30 min in 1 mM EDTA, 0.25 M phosphate buffer (pH 7.2), 7% (w/v) SDS, and hybridized overnight at 65°C in the same solution containing the denatured probe (1 X 10⁷ cpm/ml). Hybridized filters were washed twice for 30 min each at 65°C in Wash Solution One (1 mM EDTA, 40 mM phosphate buffer, pH 7.2, 5% (w/v) SDS) and three times for 30 min each at 65°C in Wash Solution Two (1 mM EDTA, 40 mM phosphate buffer pH 7.2, 1% (w/v) SDS). The air-dried filters were subjected to autoradiography (X-Omat X-ray film, Kodak) for 72h at -80°C with an intensifying screen.

Banana pulp cDNA libraries from PCI 1 and PCI 3 were each probed separately and differentially with labeled cDNA from pulp at PCI 1 and PCI 3. Plaques which demonstrated strong differential signal intensities between both probes were selected as positives. Positive plaques were then subjected to secondary screening to purify single isolates by utilizing the same probes as in the primary screening. pBluescript phagemids were excised from the isolated plaques according to the manufacturer's recommendations (Stratagene).

20 *Sequence Analysis*

Small-scale alkaline lysis plasmid preparations followed by phenol:chloroform extraction and ethanol precipitation (Sambrook et al., 1989) yielded template plasmid DNA suitable for automated sequencing. Plasmid DNA templates were sequenced, using the T3 primer, on an ABI 373A DNA sequencer (Applied Biosystems, Foster City, CA). Vector and 3' poly(A) residue sequences were removed from the output sequence. Edited sequences were loaded into the NCBI form for BLAST (9. 1) searching on a network server (www.ncbi.nlm.nih.gov), and searches were performed using the default settings of BLASTN (Altschul et al., 1990). For some cDNA clones, no significant

-25-

homology (defined as a high score above 100) with sequences in the databases was identified using BLASTN. In that event, the default settings of the BLASTX search, an algorithm that translates the nucleic acid sequence in all six frames and searches a non-redundant amino acid database for matches, were used (Gish and States, 1993).

Dot-blot Hybridization

Comparisons of the relative transcript abundance of the individual cDNA clones between PCI 1, 3 and 5 pulp were made through dot-blot hybridization experiments. Plasmids containing the cDNA inserts were affixed to nylon membrane and hybridized with first-strand cDNA from generated from PCI 1, 3 or 5 pulp RNA. The equivalent of 1×10^{11} copies of each plasmid (approximately 0.5 μ g of plasmid DNA containing a 1kb cDNA insert) was heat denatured (95°C for 10 min), and quenched on ice. Using a vacuum dot-blot apparatus (BioRad), target DNA was applied to HyBond N+ nylon membrane (Amersham). Membranes were air-dried, UV crosslinked (Stratalinker), and hybridized as described above using 2×10^6 cpm/ml of PCI 1, 3, and 5 radiolabeled first strand cDNA as probe. Following hybridization, membranes were exposed to a phosphorescent screen (PhosphorImager, Molecular Dynamics) and the scanned image was analyzed with the ImageQuant quantitation software.

Northern Analyses

Total RNA was isolated from banana pulp and peel at PCI 3, and from root, corm, and leaf tissues of greenhouse-grown Grand Nain banana plants. Ten micrograms of each of the RNA samples were separated by electrophoresis through formaldehyde-containing agarose gels and transferred to Nytran Plus nylon membrane (Schleicher and Schuell) using a vacuum transfer apparatus (BioRad) according to the manufacturer's recommendations. Equal RNA loading was confirmed by staining the RNA-containing nylon membranes with methylene

-26-

blue (Sambrook et al., 1989). The RNA blots were hybridized with a cDNA probe representing the largest isolate from each of the eleven nonredundant groups of clones. DNA probes were synthesized using the Rad-Prime DNA Labeling System (Gibco BRL), and hybridized as described above.

5

RESULTS

Differential screening of approximately 10^5 plaques with labeled pulp cDNAs resulted in the identification of approximately 100 plaques with a signal intensity sufficient to be detected by autoradiography after a 72 hour exposure to 10 X-ray film. It was apparent from the signal intensities observed between differentially hybridized plaque lifts that the relative abundance of a number of transcripts changed between PCI 1 and 3. A total of 38 cDNA clones were isolated from banana pulp libraries by differential screening.

Sequence alignment and homology searches indicate that eleven non-redundant groups of cDNAs were identified (Table 1). Using sequence 15 homology, BLAST searches were able to assign, with high scores between 167 and 1294, a putative identity for all clones. Amino acid sequence homology searches using the BLASTX algorithm were necessary to assign an identity to the clones encoding the putative lectin and senescence-related protein. According to 20 the results of the sequence homology searches, all of the banana sequences are more similar to other plant genes than to genes from other organisms. There were many redundant isolates, especially of the smaller cDNAs such as those encoding the different metallothioneins. Ten clones encoding a putative chitinase, an especially abundant protein in banana pulp (R. López-Gómez, unpublished data), 25 were isolated.

Relative abundance among the different transcripts was estimated by hybridizing isotopically labeled first-strand cDNA to an excess of cloned cDNA which was previously dot-blotted onto nylon membrane. This technique also allowed for the confirmation of differential expression of these transcripts in pulp

-27-

between PCI 1 and 3, and at a later stage of ripening, PCI 5 (Figure 1). Relative transcript abundance of starch synthase, GBSS, chitinase, and a type 2 metallothionein decreased in pulp between PCI 1 and 3, and continued to decrease through PCI 5. There was a peak in the abundance of several of the 5 transcripts in PCI 3 pulp, including endochitinase, glucanase, thaumatin, ascorbate peroxidase, and metallothionein. The differential expression of these banana transcripts before and after the peak in ethylene biosynthesis indicates that the transcripts that increase in abundance between PCI 1 and PCI 3 respond to ethylene. The differential expression of the eleven different groups of cDNAs in 10 banana pulp between ripening stages PCI 1 and 3 was confirmed by Northern analyses (data not shown). Results from the dot blot hybridization were also used to estimate relative abundance of each class of cDNA in the pulp of ripening banana fruit, with thaumatin and P-1,3-glucanase being the first and second most abundant transcripts, respectively (Figure 1).

-28-

Table I. *Genes that are differentially expressed during banana fruit ripening.* Putative cDNA identities are based on sequence homology. Number of homologous clones isolated indicated in parentheses. High scores obtained using BLASTN or BLASTX. Changes in pulp relative transcript abundance from PCI 1 - 3 indicated as "up" or "down" based on dot-blot hybridizations. Transcript sizes estimated from Northern analyses of pulp total RNA.

Homology to:	Clone	High Score [P(N) ^a]	PCI 1 to 3	Transcript size (kb)
sweet potato starch synthase (2)	pBAN 3-33	198 [6.8e-6]	down	2.2
cassava GBSS (4)	pBAN 3-18	1,121 [6.5e-95]	down	2.2
winged bean chitinase (10)	pBAN 3-30	300 [7.9e-31]	down	1.2
rice endochitinase (2)	pBAN 3-24	773 [3.4e-93]	up	1.2
soybean β -1,3-glucanase (2)	pBAN 1-3	524 [3.4e-33]	up	1.3
katemfe fruit thaumatin (2)	pBAN 3-28	635 [3.0e-125]	up	1.0
rice ascorbate peroxidase	pBAN 3-25	1,294 [4.0e-10]	up	1.1
kiwifruit metallothionein (5)	pBAN 3-6	218 [1.7e-11]	up	0.5
castor bean MT type 2 ^b (6)	pBAN 3-23	518 [2.4e-33]	down	0.6

asparagus senescence-related gene ^c	pBAN 3-46	167 [3.1e-16]	up	1.0

^a Probability of homology occurring by chance (see Altschul et al., 1990)

-29-

Although these cDNAs are relatively abundant in the pulp of banana fruit, their patterns of expression are not limited to these tissues. Northern analyses indicate that starch synthase, GBSS, and chitinase transcripts were abundant in pulp and corm tissues, and present in peel. Expression of the endochitinase, 5 thaumatin-like protein, and β -1,3 glucanase transcripts was limited to the pulp and peel of the fruit. Both classes of metallothionein transcripts were expressed in all tissues analyzed, but were most abundant in the pulp and peel. In comparison, MT was more abundant in leaves than Type-2 MT, while the converse was observed in the corm. Lectin transcripts were most abundant in pulp and root 10 tissues, whereas the ascorbate peroxidase and senescence-related protein transcripts were ubiquitously expressed.

Many of the physiological changes that occur during banana fruit ripening are in response to ethylene produced in the pulp (Don-Tinguez and Vendrell, 1993; Burdon et al., 1994). In addition, ethylene also serves as a signal for other 15 physiological changes including senescence. The cDNA clones identified in this study were isolated by differential screening at stages of fruit ripening corresponding to periods before and after the peak in ethylene biosynthesis (Agravante et al., 1991). Therefore, it is likely that some of the transcripts that increase in abundance between those stages of ripening may be regulated by 20 ethylene, even if they do not have a direct role in the ripening process. The role of ethylene in the regulation of PR proteins (glucanase, chitinase, endochitinase, thaumatin) has been well documented. Ethylene is also believed to influence expression of ascorbate peroxidase (Mehlhorn, 1990) and metallothionein (Coupe et al., 1995)

25

-30-

**EXAMPLE 2: The Abundant 31-Kilodalton Banana Pulp Protein is
Homologous to Class-III Acidic Chitinases**

The experiments described in this example were designed to identify and characterize the abundant 31kD protein from the pulp of banana fruit (*Musa acuminata* cv. Grand Nain), and to isolate a cDNA encoding this protein.

MATERIALS AND METHODS

Plant Materials

Ethylene treated and untreated banana fruit (*Musa acuminata* cv. Grand Nain) were obtained from the Northside Banana Company (Houston, TX). The pulp and peel of fruit representing each of the seven different stages of ripening (PCI 1 through 7) were separated and quick-frozen in liquid nitrogen. Tissues from ten individual fruit were pooled to obtain a uniform representative sample for each ripening stage and ground to a fine powder under liquid nitrogen in a stainless steel Waring blender. Ground samples were stored at -80°C until utilized. Other banana tissues were obtained from greenhouse-grown plants (cv Grand Nain).

Protein Isolation for Antiserum Production, N-terminal Sequencing, and Western Blotting

Soluble banana pulp proteins were differentially precipitated from pulp extracts with ammonium sulfate. P31 was most abundant in the 40 to 60% ammonium sulfate fraction, as determined by SDS-PAGE separation (Laemmli, U.K. (1970) *Nature* 227:680), followed by Coomassie blue staining (Sambrook et al. (1989) *Molecular Cloning, a Laboratory Manual*, Ed. 2 Cold Spring Harbor Press, Plainview, NY). The 31 kDa protein band was excised from the gel, homogenized and used to immunize a rabbit for antiserum production, according to standard protocols. In addition, proteins from the 40 to 60% ammonium sulfate fraction were separated by SDS-PAGE and transferred PVDF protein sequencing

-31-

membrane and stained with Coomassie blue. The stained 31 kDa protein band was excised from the membrane and the N-terminal sequence was determined.

Total protein isolated from banana root, corm, leaf, meristem, peel, and pulp at different stages of ripening were separated by SDS-PAGE and 5 electrophoretically transferred to PVDF membrane. The membranes were incubated with the primary antiserum at 1:500 dilution, and the bound antibodies were visualized using chemiluminescence.

Northern Blot Analyses

10 Total RNA was isolated from banana leaf, corm, root, peel, and floral structures and from banana pulp at PCI 1 through 7 (López-Gómez, R., et al. (1992) 5:440). Agarose gel electrophoresis, and northern blotting and hybridization were performed according to standard protocols (Sambrook et al., *supra*). The cDNA clone pBAN3-30 was radiolabeled with ^{32}P -dCTP by random 15 priming and used as a probe.

pBAN3-30 Isolation and Sequence Analysis

pBAN3-30 was isolated from a banana pulp cDNA library by differential screening (Clendennen, S.K. et al. (1997) *Plant Physiology*). The complete 20 sequence of the cDNA insert was determined on both strands, and the open reading frame was translated. Sequence homology of pBAN3-30 and the translation product (P31) were determined using the BLAST search algorithm for searching GenBank (Altschul, S.F., et al. (1990) *J. Molec. Biol.* 215:403). For the amino acid alignments, plant chitinase sequences showing significant 25 homology to P31 were downloaded from GenBank and aligned manually.

Expression of Recombinant P31

A total of ten homologous chitinase clones were isolated from the banana pulp cDNA library by differential screening, including pBAN3-30, pBAN3-31,

-32-

pBAN3-36, and pBAN3-45 (Clendennen et al., *supra*). These four clones were used for the expression of P31 for western blot analysis of the translation products. It was determined that pBAN3-36 and pBAN3-45 contained chitinase coding sequences that were in-frame with respect to β -galactosidase in the 5 pBluescript cloning vector. All four of the cDNA clones, in *E. coli* XL1-blue host cells, were grown to log phase in selective media and then induced by IPTG. Total bacterial proteins were separated by SDS-PAGE and transferred to PVDF membrane. The western blot was hybridized with P31 antiserum and visualized using chemiluminescence.

10

RESULTS

P31 Isolation and Tissue Distribution

SDS-PAGE analysis of total proteins isolated from pulp of banana fruit at seven ripening stages indicated changes in abundance of several proteins (Figure 15 1). The most abundant protein during the pre-climacteric stage (Peel Color Index or PCI 1 and 2) is a 31 kDa protein (P31) which seemed to decrease slightly in abundance as ripening proceeded (Figure 3). This protein (P31) was partially purified by a combination of ammonium sulfate precipitation and separation by SDS-PAGE. Polyclonal antiserum was raised against the purified protein. The 20 P31 antiserum recognizes a single 31 kDa polypeptide in banana pulp that is not present in banana peel, meristem, corm, or root tissue (Figure 4). These results indicate that P31 is fruit-specific.

The N-terminus of the partially purified protein was sequenced and the resultant 20-amino acid sequence is: GRNSCIGVYWGQKTDEGSLA (data also 25 appear in Figure 7). A search of the amino acid sequence databhase (GenBank) revealed that the N-terminus of P31 shares significant homology to amino-terminal peptide sequences from purified acidic chitinases of Mongolian snake-gourd (*Trichosanthes kirilowii*; see Savary et al. (1994) *Plant Physiol.* 106:1195) and chick pea (*Cicer arietinum*; see, Vogelsgang, R., et al. (1993) *Planta* 189:60).

-33-

P31 Expression in Ripening Pulp

P31 expression in banana pulp during ripening was investigated at the protein and transcript levels. Western blot analysis of banana pulp proteins isolated at each of seven chronological stages of ripening (Figure 5, top panel) indicates that P31 decreases in relative abundance during ripening, consistent with the observations of P31 abundance after separation by SDS-PAGE and staining with Coomassie blue. Using differential screening, several ripening-associated genes were isolated from a banana pulp cDNA library, including clones with significant homology to chitinases (Clendennen et al., *supra*). For determination of relative chitinase transcript abundance during ripening, total RNA was isolated from banana pulp during ripening, at PCI 1 through 7, and probed with labeled pBAN3-30. Northern blot analysis (Figure 5, bottom panel) shows that the P31 message is strongly expressed during the first few ripening stages (PCI 1 through 3) after which the chitinase transcript declines in banana pulp through the later stages of ripening. This observation is consistent with the result obtained through western analysis. Northern and western blot analysis together suggest that expression of P31 is both fruit-specific and developmentally regulated in banana. While both the P31 protein and the chitinase transcript are abundant during the pre-climacteric stages of fruit ripening (PCI 1 through 3), their relative levels decrease as ripening progresses.

pBAN3-30 Encodes P31

Three lines of evidence lead us to conclude that pBAN3-30 encodes the abundant 31 kDa pulp protein. First, the expression pattern of the pBAN3-30 transcript during ripening matches very closely with the profile of P31 abundance during ripening as determined by western blot analysis using the P31 antiserum, as seen in Figure 5. Second, the P31 antiserum recognizes the translation product of the chitinase cDNA insert. The translation products of the cDNA clones pBAN3-36 and pBAN3-45, which are homologous to pBAN3-30 but have been determined

-34-

to be in-frame with respect to the β -galactosidase gene in the pBluescript cloning vector (Stratagene), were expressed as fusion proteins with β -galactosidase. These fusion proteins were analyzed by western blotting and incubation with the P31 antiserum. The P31 antiserum recognizes a 35 kDa polypeptide produced in 5 the IPTG-induced bacterial cells containing an in-frame chitinase cDNA (pBAN3-36 and pBAN3-45) that is not present in cell extracts from bacteria containing only the pBluescript plasmid (no insert) or out-of-frame chitinase cDNA inserts (pBAN3-30 and pBAN3-31) (Figure 6). Finally, the N-terminal amino acid sequence obtained from the purified protein, which is underlined in Figure 7, is 10 identical to the deduced amino acid sequence of pBAN3-30 at 17 of 20 residues. This match is improved when the first amino acid residue, which is usually considered to be uncertain, is discounted. Despite the high sequence homology, the amino acid sequence from the partially purified protein is not completely identical to the amino acid sequence deduced from the cDNA clone pBAN3-30. It 15 is possible that a contaminating polypeptide co-migrated with P31 and influenced the amino acid sequence results. Alternatively, it is possible that P31 is encoded by a gene family in banana, members of which are highly homologous, though not identical, and cannot be distinguished from one another by northern or western analyses.

20

Sequence Analysis of pBAN3-30

The complete nucleotide sequence of pBAN3-30 and the deduced amino acid sequence of the translation product is shown in Figure 7. The cDNA insert is 1186 bp long and includes the entire chitinase coding region. The ATG beginning 25 at position 55 is likely to be the translation initiation codon because the nucleotide sequence flanking the first ATG codon matches 8 of the 12 bases in the consensus for translation start sites in plants (Joshi, C.P. (1987) *Nucl. Acids Res.* 15:6543), whereas the sequences flanking another potential in-frame downstream start site (at position 100) is identical at only 5 of the 12 bases. There is an in-frame

-35-

termination codon at position 1024 and several putative polyadenylation signals between positions 1136 and 1148.

The open reading frame spans 323 amino acids from which a translation product of 35,232 Da is predicted. A GenBank search using the full cDNA sequence reveals significant homology between pBAN3-30 and chitinase genes characterized from winged bean (*Psophocarpus tetragonolobus*, M Esaka and T. Teramoto, unpublished), cow pea (*Vigna unguiculata*, L.T.T. Vo et al., unpublished), azuki bean (*Vigna angularis*; see, Ishige, F., et al. (1993) *Plant Cell Physiol.* 34:103), maize (*Zea mays*; see, Didierjean, L., et al. (1996) *Planta* 199:1), and chick pea (*Cicer arietinum*; see, Vogelsgang, R., et al. (1993) *Plant Physiol.* 103:297). The deduced amino acid sequence of pBAN3-30 encoding P31 in banana shares sequence homology with other plant chitinases, especially with class III acidic chitinases that have been characterized from various dicots. At the amino acid level, the banana acidic chitinase amino acid sequence shows significant homology, 47-53% identity, to acidic chitinases from *Arabidopsis thaliana* (Samac, D.A., et al. (1990) *Plant Physiol.* 93:907), wine grape (*Vitis vinifera*, Busam et al, unpublished), tobacco (*Nicotiana tabacum*; see, Lawton, K. et al. (1992) *Plant Molec. Biol.* 19:735), chickpea, sugar beet (*Beta vulgaris*; see, Nielsen, K.K., et al. (1993) *Molec. Plant-Microbe Interact.* 6:495), winged bean, and cucumber (*Cucumis sativus*; see, Lawton, K.A. et al. (1994) *Molec. Plant-Microbe Interact.* 7:48).

An amino acid sequence alignment of the amino-terminal and carboxy-terminal regions of several plant acid chitinases with P31 from banana appears in Figure 8. Hydrophilicity analysis of the deduced protein sequence of P31 reveals a hydrophobic region from amino acid 1 to 25 (underlined in Figure 8A). This region may represent a signal sequence that would direct targeting to the ER. If this putative signal peptide is removed, the remaining sequence closely matches the N-terminal sequence obtained from the purified protein, which suggests that P31 is post-translationally processed. This signal peptide does not share

-36-

significant homology with the signal peptide sequences of other plant class III acidic chitinases (see Figure 8A), which are typically localized to the extracellular space (Punja, Z.K. et al. (1993) *J. Nematol.* 25:526; Collinge, D.V., et al. (1993) *Plant J.* 3:31; Lawton, K. et al. (1992) *Plant Molec. Biol.* 19:735; Graham, L.S., 5 et al. (1994) *Canad. J. Botany* 72:1057; Bol, J.F. (1990) *Ann. Rev. Phytopathol.* 28:113-138).

In addition to the N-terminal signal peptide, the banana P31 sequence is distinguished from other chitinase sequences by the presence of an 19 amino acid C-terminal extension (underlined in Figure 8B). C-terminal propeptides (CTPPs) 10 have been identified in a number of monocot and dicot polypeptides that direct proteins to the plant vacuole. Among others, CTPPs have been characterized in vacuolar lectins from barley and rice, and from vacuolar β -1,3-glucanase and chitinase from tobacco (see, Bednarek, S.Y. (1992) *Plant Molec. Biol.* 20:133, for review). In general there is little sequence homology among plant vacuolar 15 targeting sequences. However, weak homology can be detected between the C-terminal extension of P31 (SNILSMP) and vacuolar targeting sequences that have been characterized in the sweet potato storage protein sporamin (NPIRLP) (Linhorst, H.J.M. (1991) *Crit. Rev. Plant Sci.* 10:123) and in a 2S albumin from Brazil nut (NLSPMRCP) (Saalbach, G. et al. (1996) *Plant Physiol.* 112:975).

20 Based on amino acid sequences, chitinases can be grouped into four classes. Class I includes a majority of chitinases described, possessing an N-terminal cysteine-rich lectin or "hevein" (chitin-binding) domain and a highly conserved catalytic domain. Class II chitinases lack the N-terminal cysteine-rich domain but have a high amino acid sequence identity to the main structure of class 25 class I chitinases. Class III chitinases show little sequence similarity to plant enzymes in class I or II, but may in fact be more similar to bacterial chitinases. The majority of class III chitinases are classified as such on the basis of homology to previously described lysozymes with chitinase activity. Class IV chitinases contain a cysteine-rich domain and conserved main structure which resemble those

-37-

of class I chitinases by are significantly smaller due to four deletions (Punja, Z.K., et al. (1993) *J. Nematol.* 25:526; Collinge, D.V., et al. (1993) *Plant J.* 3:31; Graham, L.S., et al. (1994) *Canad. J. Botany* 72:1057). Although the banana pulp chitinase shares significant sequence homology with other plant class III acidic chitinases, the predicted isoelectric point of P31 is 7.63 (neutral). In addition, studies to determine the chitinase active sites in bacterial chitinases appear to be conserved in plant, bacterial, and fungal sequences (Perlick, A.M., et al. (1996) *Plant Physiol.* 110:147). At least five highly conserved amino acids have been shown to be necessary for chitinase activity, and the deduced amino acid sequence of P31 indicates that only three of the five amino acids necessary for chitinase activity are conserved in banana P31 (not shown) (Watanabe, T., et al. (1993) *J. Biol. Chem.* 268:18567; Tsujibo, H., et al. (1993) *Biosci. Biotech. Biochem.* 57:1396).

15 *Role of chitinase in banana pulp*

In plants, class III chitinases have been reported to be induced in response to various stresses such as pathogenesis and wounding (Ishige, F., et al. (1993) *Plant Cell Physiol.* 34:103; Lawton, K., et al. (1992) *Plant Molec. Biol.* 19:735; Nielsen, K.K., et al. (1993) *Molec. Plant-Microbe Interact.* 6:495; Lawton, K.A., et al. (1994) *Molec. Plant-Microbe Interact.* 7:48; Mehta, R.A., et al. (1991) *Plant Cell Physiol.* 32:1057). Recently, it has been reported that the expression of several pathogenesis and stress-related proteins, including chitinases, is associated with fruit ripening. Several genes encoding pathogenesis-related proteins such as endochitinase are associated with ripening in banana pulp (Clendennen, S.K., et al. (1997) *Plant Physiol.*). Considering the antifungal activity that they exhibit in other plants, it is possible that chitinases fulfill a protective role during fruit development and ripening. However, in contrast to the ripening-associated PR-proteins studied in cherry, avocado, and tomato, banana P31 decreases in abundance during ripening. Although it is possible that the banana chitinase

-38-

serves a protective role during fruit development, an alternate hypothesis is that the chitinase in banana pulp has been recruited to serve as a storage protein in this tissue.

Storage proteins are a heterogeneous group of proteins for which no 5 defined assay is available. According to a recent review (Staswick, P.E. (1994) *Ann. Rev. Plant Physiol. Plant Molec. Biol.* 45:303), storage proteins generally share the features listed below; we relate traits of P31 to general features of storage proteins.

1) *Storage proteins are very abundant.* We have found P31 to be very 10 abundant in unripe banana pulp, accounting for approximately 20 to 30% of total soluble pulp protein. 2) *Storage proteins are preferentially degraded during a subsequent developmental stage.* For example, a vegetative storage protein characterized from the bark of poplar trees accumulates during fall and winter and is degraded during shoot growth in the spring. P31 is preferentially degraded 15 during banana fruit ripening. Both the transcript and protein abundance decrease during ripening. If P31 is indeed a storage protein in banana pulp, this preferential degradation implies the existence of a protease specific to the storage protein, and inhibition of the protease would inhibit degradation of the storage protein. 3) *Storage proteins are generally localized in storage vacuoles within the 20 cell.* The sub-cellular localization of P31 has not yet been determined. According to the deduced amino acid sequence of P31, there is a putative signal peptide sequence for P31 that is 25 amino acids long and hydrophobic. In addition, the amino acid sequence of P31 from banana pulp is distinguished from other plant class III acid chitinases by the presence of an 18 amino acid C-terminal extension 25 that shows some homology to previously characterized C-terminal vacuolar targeting signals, suggesting vacuolar localization of P31. 4) *Many storage proteins contain a large proportion of amino acid residues with nitrogen-containing R-groups.* Amino acid composition analysis of P31 indicates that 22% of residues have N-containing R-groups (Trp, Gln, Asn, Lys, Arg, His). This is

-39-

approximately the same proportion of N-containing amino acids in vegetative storage proteins from soybean and poplar (21-25%). Interestingly, the amino acid composition of P31 is not significantly higher than the N- of other plant chitinases (17-23%). 5) *Storage proteins typically lack any other metabolic or structural role.* However, this is not necessarily true for soybean vegetative storage protein, which has retained a minimal acid phosphatase activity, and patatin, a potato tuber storage protein that exhibits residual lipid acyl hydrolase activity. Preliminary evidence suggests that protein extracts from banana pulp have very low chitinase activity, as measured by soluble chitobiose released from radiolabeled chitin. In 10 addition, only three of the five amino acids which have been determined to be essential for chitinase activity are conserved in P31. Taken together, this evidence lends support to the hypothesis that P31, while sharing sequence homology with plant chitinases, may actually be serving as a storage protein in banana pulp.

15

EXAMPLE 3: A Novel Fruit-Associated Class of Metallothionein-Like Proteins from Banana (*Musa acuminata* cv Grand nain): Characterization of the gene family and induction by H₂O₂

In the experiments described in this Example, the gene family encoding the 20 fruit-associated MTs is characterized, and sequence and functional evidence is provided that at least one member functions as an antioxidant during fruit ripening.

MATERIALS AND METHODS

25 *Plant Materials*

Ethylene treated and untreated banana fruit (*Musa acuminata* cv. Grand Nain) were obtained from the Northside Banana Company (Houston, TX). The pulp and peel of fruit representing different stages of ripening (PCI 1 and 3) were separated and quick-frozen in liquid nitrogen. Tissues from ten individual fruit

-40-

were pooled to obtain a uniform representative sample for each ripening stage and ground to a fine powder under liquid nitrogen in a stainless steel Waring blender. Ground samples were stored at -80°C until utilized. Leaf, corm and root tissue were obtained from greenhouse-grown plants (cv Grand Nain), ground in liquid 5 nitrogen using a mortar and pestle, and stored at -80°C.

RNA Isolation and Northern Blotting

Pre-warmed (65°C) RNA extraction buffer (1.4% (w/v) SDS, 2% (w/v) polyvinylpyrrolidone, 0.5 M NaCl, 0.1M sodium acetate, 0.05 M EDTA (pH 8.0) 10 0.1% (v/v) β-mercaptoethanol) was added to previously ground samples of pulp at a ratio of 5 ml buffer per gram of tissue. Samples were homogenized with several short bursts of a tissue homogenizer (Polytron, Brinkman) and incubated at 65°C for 15 min. Starch and other cell debris were pelleted by centrifugation at 2,400g for 10 min at room temperature and the supernatant transferred to a disposable 15 polypropylene tube. After the addition of 0.2 vol. of 5 M potassium acetate (pH 4.8), the samples were mixed and incubated on ice for 30 min. The resulting precipitate was pelleted by centrifugation at 20,200 rpm for 10 min at 4°C in a Sorvall SW28 rotor. The supernatant was transferred to a disposable polypropylene centrifuge tube, and the high-molecular weight RNAs were 20 precipitated by the addition of lithium chloride to a final concentration of 2.5 M and incubation overnight at 4°C.

RNA was extracted from previously frozen ground peel, root, leaf, and corm tissue using CTAB extraction.

Five micrograms of total RNA from root, corm, and leaf tissue of 25 greenhouse-grown plants, and from peel and pulp (PCI 3) were separated by electrophoresis in formaldehyde-containing 2% agarose gels and transferred to nylon membrane (Nytran Plus, Schleicher and Schuell) using 20X SSPE as a transfer buffer and a vacuum transfer apparatus (Bio-Rad). Equal RNA loading was confirmed by staining the RNA on the nylon membranes with methylene blue

-41-

(Sambrook et al., 1989). RNA blots were prehybridized in 1 mM EDTA, 0.25 M phosphate buffer (pH 7.2), 7% (w/v) SDS, and hybridized overnight at 65°C in the same solution containing the denatured probe (1 X 10⁷ cpm/ml). Hybridized filters were washed twice for 30 min each at 65°C in Wash Solution One [1 mM
5 EDTA, 40 mM phosphate buffer (pH 7.2) 5% (w/v) SDS] and three times for 30 min each at 65°C in Wash Solution Two [1 mM EDTA, 40 mM phosphate buffer (pH 7.2), 1% (w/v) SDS]. The air-dried filters were subjected to autoradiography (X-Omat X-ray film, Kodak) at -80°C with an intensifying screen. The RNA blots were hybridized with a cDNA probe representing either the MT cDNA clone
10 isolated from library 1 or 3, using the Rad-Prime DNA Labeling System (Gibco BRL) to label the DNA probes.

Genomic DNA isolation and Southern Blotting

Leaf tissue was ground with a mortar and pestle under liquid nitrogen and
15 added to a tube containing pre-warmed (65°C) DNA isolation buffer. The mixture was incubated at 65°C for 30 minutes, then extracted twice with an equal volume of chloroform. After the second extraction, DNA was precipitated from the aqueous phase by the addition of an equal volume of isopropanol, and mixed by gently inverting the tube. DNA was pelleted by centrifugation, washed with
20 70% ethanol, dried briefly, and resuspended in TE (pH 8.0). DNA samples were treated with RNase, then phenol extract with TE buffered phenol by rocking gently, chloroform extracted, and precipitated with 2.5 vol ethanol.

For the genomic Southern blots, 15 µg of genomic DNA was digested with restriction endonucleases BamHI, HinDIII, EcoRI, PstI, and SalI (Promega), and
25 restriction fragments were separated by electrophoresis on a 0.7% agarose gel. DNA in the gel was denatured (1.5 M NaCl, 0.5 M NaOH) and neutralized (1.5 M NaCl, 0.5 M Tris, pH 8.0) before being transferred to nylon membrane (S&S Nytran Plus) using a BioRad vacuum transfer apparatus. DNA was covalently crosslinked to membrane by UV irradiation (Stratalinker, Stratagene), and the

-42-

membrane was hybridized separately with probes corresponding to the MT cDNA clones isolated from the banana pulp cDNA libraries from PCI 1 and 3 (MT-F1 and MT-F3).

5 *Genomic library screening and mapping*

Approximately 6×10^5 primary plaques from a *Musa acuminata* cv Grand Nain λ FIX genomic library (Stratagene) were screened with the MT cDNA probe isolated from the PCI pulp cDNA library (MT-F1). Plaque-lifts containing filter-bound λphage DNA was denatured for two min in 1.5 M NaCl, 0.5 M NaOH, 10 and neutralized for four minutes in 1.5 M NaCl, 0.5 M Tris (pH 8.0). Filters were rinsed in 0.5 M Tris (pH 8.0), blotted dry, and the DNA was covalently crosslinked to the filters by UV irradiation (Stratalinker, Stratagene). Plaque-lifts were hybridized as described previously. Twenty-four positives were plaque purified, and λphage DNA was isolated for generating maps of the region 15 containing the MT gene. Southern blot analysis was used to determine the identity of the MT clone according to diagnostic restriction sites. Fragments of the genomic clones containing the coding region and 5' and 3' flanking region were subcloned into pBluescript KS, and subclones were mapped and sequenced.

20 *Sequencing and Data Analysis*

Small-scale alkaline lysis plasmid preparations followed by phenol:chloroform extraction and ethanol precipitation (Sambrook et al., 1989) yielded template plasmid DNA suitable for automated sequencing. Plasmid DNA templates were sequenced, using the T3 primer, on an ABI 373A DNA sequencer 25 (Applied Biosystems, Foster City, CA).

Using the BLASTX search algorithm, it was determined that the banana cDNA clones shared significant sequence homology with MT cDNA clones isolated from other fruit. The deduced amino acid sequences of plant MT cDNA clones were aligned using Clustal. A dendrogram showing the relationship among

-43-

several different classes of plant MTs was generated from the deduced amino acid sequences using Clustal.

Protoplast isolation and dot blot analysis of MT transcript abundance

5 Protoplasts from banana pulp at PCI 4 were isolated as described in Khalid et al. (in preparation). 1 X 10⁵ protoplasts were incubated under experimental conditions for 4h at room temperature in protoplast isolation buffer (Khalid et al. 1997), with gentle rocking to keep the cells suspended. The treatments included incubation with different concentrations of ascorbate (buffered to pH 7.0), CuCl₂,
10 and hydrogen peroxide from 1 to 100 mM. After the incubation, a crude RNA preparation from the protoplasts was spotted onto nylon membrane in duplicate. One membrane was hybridized to the F3 cDNA probe to determine relative transcript abundance of fruit-associated MT. The second membrane was hybridized with an 18S ribosomal RNA probe to assess RNA loading. The
15 membranes were then exposed to a phosphorescent screen (PhosphorImager, Molecular Dynamics) and the scanned images were quantified with the ImageQuant software. The relative abundance was normalized to the measure of total RNA loaded, and is expressed in arbitrary units.

20 RESULTS

The cDNA sequence of the banana fruit-associated MT clones is shown in Figure 9. The clones were isolated by differential screening of pulp cDNA libraries (Clendennen and May, 1997). F1 was isolated from the PCI1 library, whereas F3 was isolated from the PCI3 library. The cDNA clones are slightly
25 variable in size, and most of the differences in size and primary sequence occurs in the 3' untranslated region (UTR), with F1 having approximately 70 more bases than F3. The two banana cDNA sequences are 60% identical at the nucleotide level, and 81% identical within the coding region.

-44-

While both of the banana fruit-associated MT polypeptides are 65 amino acids, the two cDNA clones encode distinct polypeptides. The N-terminal and C-terminal domains are well conserved, and separated by a variable spacer. In Figure 10A, an alignment of deduced amino acid sequences shows the degree of similarity among the different fruit-associated MTs from banana, kiwifruit, papaya, and apple. In panel B, the relationships among a variety of plant MTs is depicted in a dendrogram generated from a cluster together, as do the type 1 MT sequences. The fruit-associated MT sequences (banana, kiwifruit, papaya, and apple) cluster together and are distinct from both type I and type 2 plant MTs.

Despite the sequence similarity, the size difference between the transcripts of the two banana MT cDNA clones allows them to be separated on a high percentage (2%) agarose gel and detected by northern blotting and hybridization separately with each probe (Figure 11). Transcript sizes of F1 and F3 as determined from northern analysis are approximately 540 and 430 bases, respectively. The larger transcript (F1) is abundant in pulp, peel, and corm. It is also present in low abundance in banana leaves, but is not detected in roots. The smaller transcript (F3) is most abundant in leaves, present in pulp and peel, and barely detectable in root and corm tissue.

Southern analysis using both cDNAs as probes indicates the presence of up to five copies of the fruit type MT - two copies with homology to F1 and three copies with homology to F1 (data not shown). Twenty-four genomic clones of fruit MT were isolated from the genomic library, and restriction maps of the region containing the MT gene indicated that three distinct genes had been isolated. Clones representing both the F1 and F3 cDNA clones were isolated from the genomic library, as well as a gene with homology to the fruit-associated MT F!, but for which no cDNA clone has been isolated (named MT-F1b). Subclones of these different MT genes were generated and the region containing the coding region as well as 5' and 3' flanking regions were mapped. Maps of the different MT genes, including the coding region and at least 1kb of 5' and 3'

-45-

flanking regions appear in Figure 12. Based on mapping and sequence data it can be determined that the MT F3 gene is comprised of three exons separated by two introns. The mapping resolution was not fine enough to determine the existence or position of introns in the other MT genes. The nucleotide sequence of the F3
5 genomic clone from the HindIII site to the SalI site, which includes the complete coding region, is depicted in Figure 13. Several features of the sequence are highlighted in the figure, including a 10-base 5' sequence motif beginning at -313 from the translation start site (in capital letters) that shares homology with an antioxidant response element. The putative TATA-box (starting at position -96
10 from the translation start site) is underlined, and the three exons (beginning from the translation start site) are depicted in capital letters. At the 3' end of the sequence, the stop codon is underlined, as well as a potential polyadenylation signal (TAAATAAA).

Because of the putative ARE identified in the 5' flanking sequence, the
15 effect of antioxidants (ascorbate), oxidizing agents (H_2O_2), and metal ions (Cu^{++}) on MT transcript abundance was determined in banana pulp protoplasts. H_2O_2 , but not copper ions, resulted in dramatic and dose-dependent increase in the relative abundance of the fruit-associated MT transcript (Figure 14). The presence of ascorbate resulted in a reduction in the relative MT transcript abundance as
20 compared to an untreated control.

DISCUSSION

Eleven non-redundant groups of ripening-associated cDNA clones were isolated from banana pulp cDNA libraries by differential screening and identified
25 by sequence homology (Clendennen and May, 1997). One of the groups of cDNA clones includes a previously uncharacterized type of metallothionein (MT), the transcript of which is found abundantly in ripening banana pulp. There are two classes of this ripening-associated MT transcript in banana pulp that vary in primary sequence and in size. Both the larger (F1) and the smaller (F3)

-46-

transcripts increase in abundance in banana pulp during ripening, but F1 increases more dramatically than F3. In addition, the tissue distribution of these transcripts differs: MT-F1 is expressed abundantly in the pulp and peel, and slightly in corm tissue, whereas MT-F3 is expressed abundantly in pulp, peel, and leaves, and very
5 slightly in roots. Based on the isolation of two distinct cDNA clones, it was suspected that the fruit-associated MTs were encoded by a small gene family. Southern analysis confirmed this, and suggested the presence of up to five members of the fruit-associated MT gene family in banana. Three different MT genes were identified after screening twenty-four genomic clones that hybridized
10 to F1 and F3 cDNA probes, as determined by restriction mapping of the segment containing the coding region. Genomic clones representing both cDNA clones were isolated.

While the invention has been described and illustrated herein by references
15 to various specific material, procedures and examples, it is understood that the invention is not restricted to the particular material, combinations of material, and procedures selected for that purpose. Numerous variations of such details can be implied and will be appreciated by those skilled in the art.

-47-

WHAT IS CLAIMED IS:

1. An isolated and purified banana DNA molecule, said DNA molecule being differentially expressed during banana fruit development.
- 5 2. A DNA molecule according to claim 1, wherein said DNA molecule encodes a protein selected from the group consisting of a starch synthase, a granule-bound starch synthase, a chitinase, an endochitinase, a beta-1,3 glucanase, a thaumatin-like protein, an ascorbate peroxidase, a metallothionein, a lectin, and another senescence-related protein.
10 3. A DNA molecule according to claim 1, selected from the group consisting of clones pBAN 3-33, pBAN 3-18, pBAN 3-30, pBAN 3-24, pBAN 1-3, pBAN 3-28, pBAN 3-25, pBAN 3-6, pBAN 3-23, pBAN 3-32, and pBAN 3-46.
- 15 4. A DNA molecule according to claim 1, wherein said DNA molecule has the nucleotide sequence selected from the group consisting of SEQ ID NO: 1, SEQ ID NO: 2, and SEQ ID NO: 3.
20 5. A DNA molecule according to claim 1, wherein said DNA molecule encodes a protein having an amino acid sequence selected from the group consisting of SEQ ID NO: 4, SEQ ID NO: 5, SEQ ID NO: 6, the DNA sequence shown in Figure 16, the DNA sequence shown in Figure 17, the DNA sequence shown in Figure 18, and the DNA sequence shown in Figure 19.
- 25 6. A chimeric gene comprising a DNA molecule which is differentially expressed during banana fruit development operably linked to a heterologous promoter.
7. A replicable expression vector comprising the chimeric gene of claim 6..

-48-

8. A plant genome, comprising the chimeric gene of claim 6.
9. A plant cell, comprising the chimeric gene of claim 6.
- 5 10. A plant comprising the chimeric gene of claim 6, wherein said chimeric gene is stably integrated into the plant genome.
11. An isolated and purified banana protein which is differentially produced in developing banana fruit.
- 10 12. A protein according to claim 11, wherein said protein is a selected from the group consisting of a starch synthase, a granule-bound starch synthase, a chitinase, an endochitinase, a beta-1,3 glucanase, a thaumatin-like protein, an ascorbate peroxidase, a metallothionein, a lectin, and another senescence-related protein.
- 15 13. A protein according to claim 11, wherein said protein is encoded by a DNA molecule selected from the group consisting of clones pBAN 3-33, pBAN 3-18, pBAN 3-30, pBAN 3-24, pBAN 1-3, pBAN 3-28, pBAN 3-25, pBAN 3-6, pBAN 3-23, pBAN 3-32, and pBAN 3-46.
- 20 14. A protein according to claim 11, wherein said protein has an amino acid sequence selected from the group consisting of SEQ ID NO: 4, SEQ ID NO: 5, SEQ ID NO: 6, the amino acid sequence shown in Figure 16, the amino acid sequence shown in Figure 17, the amino acid sequence shown in Figure 18, and the amino acid sequence shown in Figure 19.
- 25 15. A composition comprising the protein of claim 11 and a carrier therefor.

-49-

16. A plant cell comprising the protein of claim 11.
17. An isolated and purified banana DNA regulatory element which is 5' or 3' to a gene which is differentially expressed during banana fruit development.
5
18. A regulatory element according to claim 17, wherein said regulatory element is activated by an ethylene signal.
19. A regulatory element according to claim 18, wherein the ethylene signal is produced by developing fruit.
10
20. A regulatory element according to claim 18, wherein the ethylene signal is produced by exogenous ethylene gas.
- 15 21. A chimeric gene comprising a banana DNA regulatory element operably linked to a heterologous DNA molecule, wherein said regulatory element is naturally found 5' or 3' to a gene which is differentially expressed during banana fruit development.
- 20 22. A plant genome comprising a chimeric gene according to claim 21.
23. A plant cell transformed with a chimeric gene according to claim 21.
24. A plant comprising a chimeric gene according to claim 21, wherein said chimeric gene is stably integrated into the plant genome.
25
25. A method for expression of heterologous protein in fruit comprising transforming fruiting plants with a chimeric gene according to claim 21, exposing

-50-

said fruit to an plant development signal, and harvesting fruit containing said heterologous protein.

26. The method of claim 25, wherein the plant development signal is ethylene
5 gas produced by ripening fruit.

27. The method of claim 25, wherein the plant development signal is exogenous ethylene gas.

10 28. The method of claim 25, further comprising the step of isolating the heterologous proteins from the harvested fruit.

29. The method of claim 25, wherein the heterologous protein is a therapeutic protein

15 30. A fruit produced by the method of claim 25.

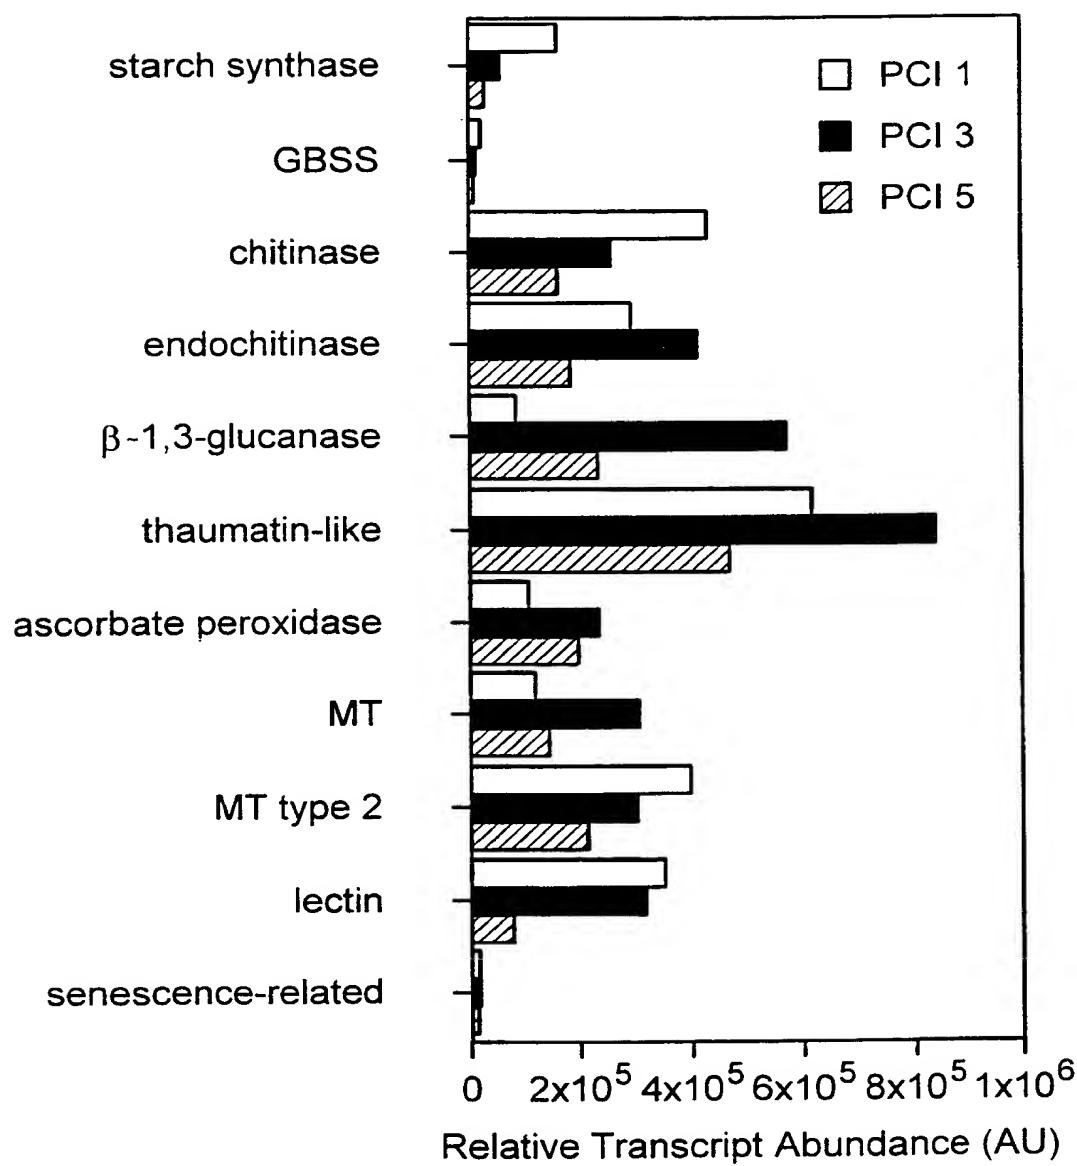

31. The fruit of claim 30, wherein said fruit is a banana.

20 32. A protein produced by the method of claim 25.

33. A protein produced by the method of claim 28.

INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 98/03343

A. CLASSIFICATION OF SUBJECT MATTER

IPC 6	C12N15/29	C12N15/53	C12N15/54	C12N15/55	C12N15/82
	C12N9/08	C12N9/10	C12N9/24	C12N5/10	C07K14/415
	C07K14/42	C07K14/825	A01H5/00		

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12N C07K A01H

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category °	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	CLENDENEN S K ET AL: "ISOLATION AND IDENTIFICATION OF GENES DIFFERENTIALLY EXPRESSED DURING BANANA FRUIT RIPENING" PLANT PHYSIOLOGY, vol. 111, no. 2, June 1996 (1996-06), page 34 XP002049413 abstract	1
A	---	2,3, 6-13, 15-33
X	MEDINA-SUAREZ R ET AL: "GENE EXPRESSION IN BANANA PEEL AND PULP DURING RIPENING" PLANT PHYSIOLOGY, vol. 111, no. 2, June 1996 (1996-06), page 122 XP002049412 abstract	1
A	---	2,3, 6-13, 15-33
	-/-	

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

° Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

Date of the actual completion of the international search

19 March 1999

Date of mailing of the international search report

05.08.99

Name and mailing address of the ISA

INTERNATIONAL SEARCH REPORT

ational application No.

PCT/US 98/03343

Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:

2. Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of Item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

See additional sheet.

1. As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

See extra sheet, Invention 1.

Remark on Protest

- The additional search fees were accompanied by the applicant's protest.
 No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International Application No. PCT/US 98/03343

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

1. Claims: 1-3,6-13,15-33 partially

An isolated and purified banana DNA molecule being differentially expressed during banana fruit development, especially being a starch synthase, corresponding to pBAN3-33 or pBAN 3-18, and the corresponding protein. Chimeric genes, vectors, compositions, plant cells and plants comprising said DNA molecules or proteins. A regulatory element of banana which is 5' or 3' to a gene differentially expressed during banana fruit development, activated by ethylene, chimeric genes, plant cells, and plants comprising said element. A method for the expression of a heterologous protein in fruit employing said chimeric genes, preferably for the expression and purification of a therapeutic protein, fruit and protein produced thereby.

2. Claims: 1-3,5-33 partially; 4 completely

idem, the DNA sequence encoding a chitinase or endochitinase, preferably corresponding to pBAN 3-30, pBAN3-24, SEQ ID NO:1-3, Fig. 16,17; the protein corresponding to SEQ ID NO: 4-6

3. Claims: 1-3,6-13,15-33 partially

idem, the DNA sequence encoding a beta-1,3 glucanase, preferably corresponding to pBAN 1-3

4. Claims: 1-3,6-13,15-33 partially

idem, the DNA sequence encoding a thaumatin-like protein, preferably corresponding to pBAN 3-28

5. Claims: 1-3,6-13,15-33 partially

idem, the DNA sequence encoding an ascorbate peroxidase, preferably corresponding to pBAN 3-25

6. Claims: 1-3,5-33 partially

idem, the DNA sequence encoding a metallothionein, preferably corresponding to pBAN 3-6, pBAN3-23, Fig. 18,19

7. Claims: 1-3,6-13,15-33 partially

idem, the DNA sequence encoding a lectin, preferably corresponding to pBAN 3-32

INTERNATIONAL SEARCH REPORT

International Application No. PCT/US 98/03343

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

8. Claims: 1-3,6-13,15-33 partially

idem, the DNA sequence encoding a senescence-related protein, preferably corresponding to pBAN 3-46
